 $\operatorname{Proj}_{\mathcal{M}}(\mathbf{A})$ the projection of \mathbf{A} onto the set \mathcal{M}

Chapter 1

Week1

1.1. Tuesday

The Markov Chains course mainly focus on the performance analysis for which the Markov decision is made.

1.1.1. News Vendor Problems

A store sells perishable iterms (newpapers) with:

- Selling price $c_p = 1$
- Variable cost $c_v = 0.25$
- Salvage value $c_s = 0$

The aim is to decide how many copies should be ordered. Before making the decision, we need to estimate the demand.

Suppose the demand *D* has the following distribution:

$$d$$
 10 15 20 25 30 \mathbb{P} 1/4 1/8 1/8 1/4 1/4

Hence, the profit for the day i is given by:

profit per day =
$$min(q, D_i)c_p - qc_v$$
,

with *q* being the number of copies ordered.

More generally, for $c_s \neq 0$, the profit for the day i is

profit per day =
$$\min(q, D_i)c_p - qc_v + \max(q - D_i, 0)c_s$$
,

Hence, our objective is to maximize the expected profit for a day

$$h(q) = \mathbb{E}_D \operatorname{Profit}(q, D)$$

$$= c_p \mathbb{E}_D \min(q, D) - c_v q + c_s \mathbb{E}_D \max(q - D, 0)$$
(1.1)

Chapter 2

Week2

2.1. Tuesday

2.1.1. Optimal order quantity

The optimal y^* is the smallest y such that

$$F(y) \ge \frac{c_p - c_v}{c_p - c_s}$$

Discrete Case Optimization. Given the expected profit function h(y), we want to find the optimal y. Note that y cannot be optimal if h(y+1) - h(y) > 0.

$$h(y+1) - h(y) = \mathbb{E}\operatorname{profit}(y+1,D) - \operatorname{profit}(y,D)$$

= $\mathbb{E}\operatorname{revenue}(y+1,D) - \operatorname{revenue}(y,D) - c_v$

If $D \ge y + 1$, there will be no leftover iterms in both systems:

$$revenue(y+1,D) - revenue(y,D) = c_p$$

If $D \leq y$,

$$revenue(y+1,D) - revenue(y,D) = c_s$$

It follows that

$$h(y+1) - h(y) = c_p \mathbb{P}[D \ge y+1] + c_s \mathbb{P}[D \le y] - c_v$$

= $c_p - c_v - (c_p - c_s) \mathbb{P}[D \le y]$

Hence, h(y+1) > h(y) iff

$$\mathbb{P}[D \le y] < \frac{c_p - c_v}{c_v - c_s}$$

In this case y cannot be optimal. Hence, y^* is the smallest y s.t.

$$\mathbb{P}[D \le y] \ge \frac{c_p - c_v}{c_v - c_s}$$

Holding Cost for h = .1. If each leftover item cost h, we have

$$\mathbb{E}\operatorname{Profit}(q,D) = \mathbb{E}\min(q,D)c_p - c_v q - h\mathbb{E}(q-D)^+$$

In addiction, if given a fixed cost of order c_f , we derive

$$\mathbb{E}\operatorname{Profit}(q,D) = \mathbb{E}\min(q,D)c_p - c_vq - h\mathbb{E}(q-D)^+ - c_f$$

Confidence Interval. The expected profit in next three months is a summation of 90 i.i.d. RVs:

$$R(25) = P_1(25) + \cdots + P_{90}(25)$$

Using central limit theorem, this RV is approximatly normal. It follows that

$$R(25) \sim \mathcal{N}(11812, 90\sigma^2)$$

where $\sigma^2 = Var(R(25))$. Hence,

$$\mathbb{P}\left(\left|\frac{R(25) - 11812}{\sqrt{90}\sigma}\right| < 1.96\right) = 0.95$$

With 95% level of confidence, R(25) is between $11812+1.96\cdot\sqrt{90}\sigma$ and $11812-1.96\cdot\sqrt{90}\sigma$

2.1.2. Non-perishable Products

1. For $X_n \ge s$, do not order anything

2. Otherwise, order enough to bring the inventory level to *S* at the beginning of the next period.

For example, (s,S) = (20,30), determine the probability $\mathbb{P}\{X_10 = 10 \mid X_9 = 10\}$ and $\mathbb{P}\{X_10 = 10 \mid X_9 = 20\}$:

$$\mathbb{P}\{X_{10} = 10 \mid X_9 = 10\} = \mathbb{P}(D_{10} = 20) = \frac{1}{8}$$

$$\mathbb{P}\{X_{10} = 10 \mid X_9 = 20\} = \mathbb{P}(D_{10} = 10) = \frac{1}{4}.$$

Actually, we can create a matrix to describe these conditional probabilities:

$$S_{ij} = \mathbb{P}\{X_{10} = j \mid X_9 = i\}$$
